

QWEN <-> V-JEPA alignment DOWN the semantic spectrum across the cohort (deeper axes)

groundedness down the spectrum (per subject + mean)

alignment down the spectrum (per subject + mean)

DEEPER AXES across subjects -- walking down the shared PC spectrum (falling explained variance), does visual groundedness (brain-independent $CV R^2$, left) and voxel-space alignment (right) fall off, and WHERE? The top PCs are strongly grounded; the interesting point is where a language-derived dimension stops being recoverable from vision -- and whether that point is consistent across subjects.

WHAT WE EXPECT (and why): A drop STEEPER than the EVR roll-off marks a reliable-but-ungrounded (language-specific) axis; a flat-high curve means vision recovers even fine semantic structure. Consistency across subjects is the readout, not a group mean.

READING (candidate; the call is yours): RESULT: groundedness/alignment down 10 PCs across 7 subjects.
