

\$2 model-side gates -- forward-vs-backward signal per band, three metrics

MODEL-SIDE GATES (\$2; pre-brain, from V-JEPA features alone). Gate 1: the ERROR band must DIFFER forward vs backward (high video-specific diff/content ratio) -- the model has causal structure to offer. Gate 2: the ENCODER band must NOT differ much (high $\cos(\text{fw}, \text{rv})$) -- it is a content model. decode acc (vs 0.5) measures a SHARED direction axis; ~ 0.5 with a high diff/content ratio means the direction is VIDEO-SPECIFIC, not a global axis.

READING (candidate; the call is yours): GATE 1 (error carries direction): PASS. GATE 2 (encoder is content): PASS. Direction lives in the error LATENT marginal (low cos, high ratio), not the spatial map; decode $\sim$ chance $\Rightarrow$ the signal is video-specific, consistent with the prior weak direction main effect.
